

# CalorieCaptorGlass: Food Calorie Estimation Based on Actual Size using HoloLens and Deep Learning

Shu Naritomi, Keiji Yanai

Demo ID: 1005

The University of Electro-Communications, Tokyo, Japan

## Background

- There are many studies on applications that estimate calories from images.
- There is a **issue**.
  - Manual entry of volumes is required for each meal.
  - Limitation of category number.
  - Restrictions on shooting methods.

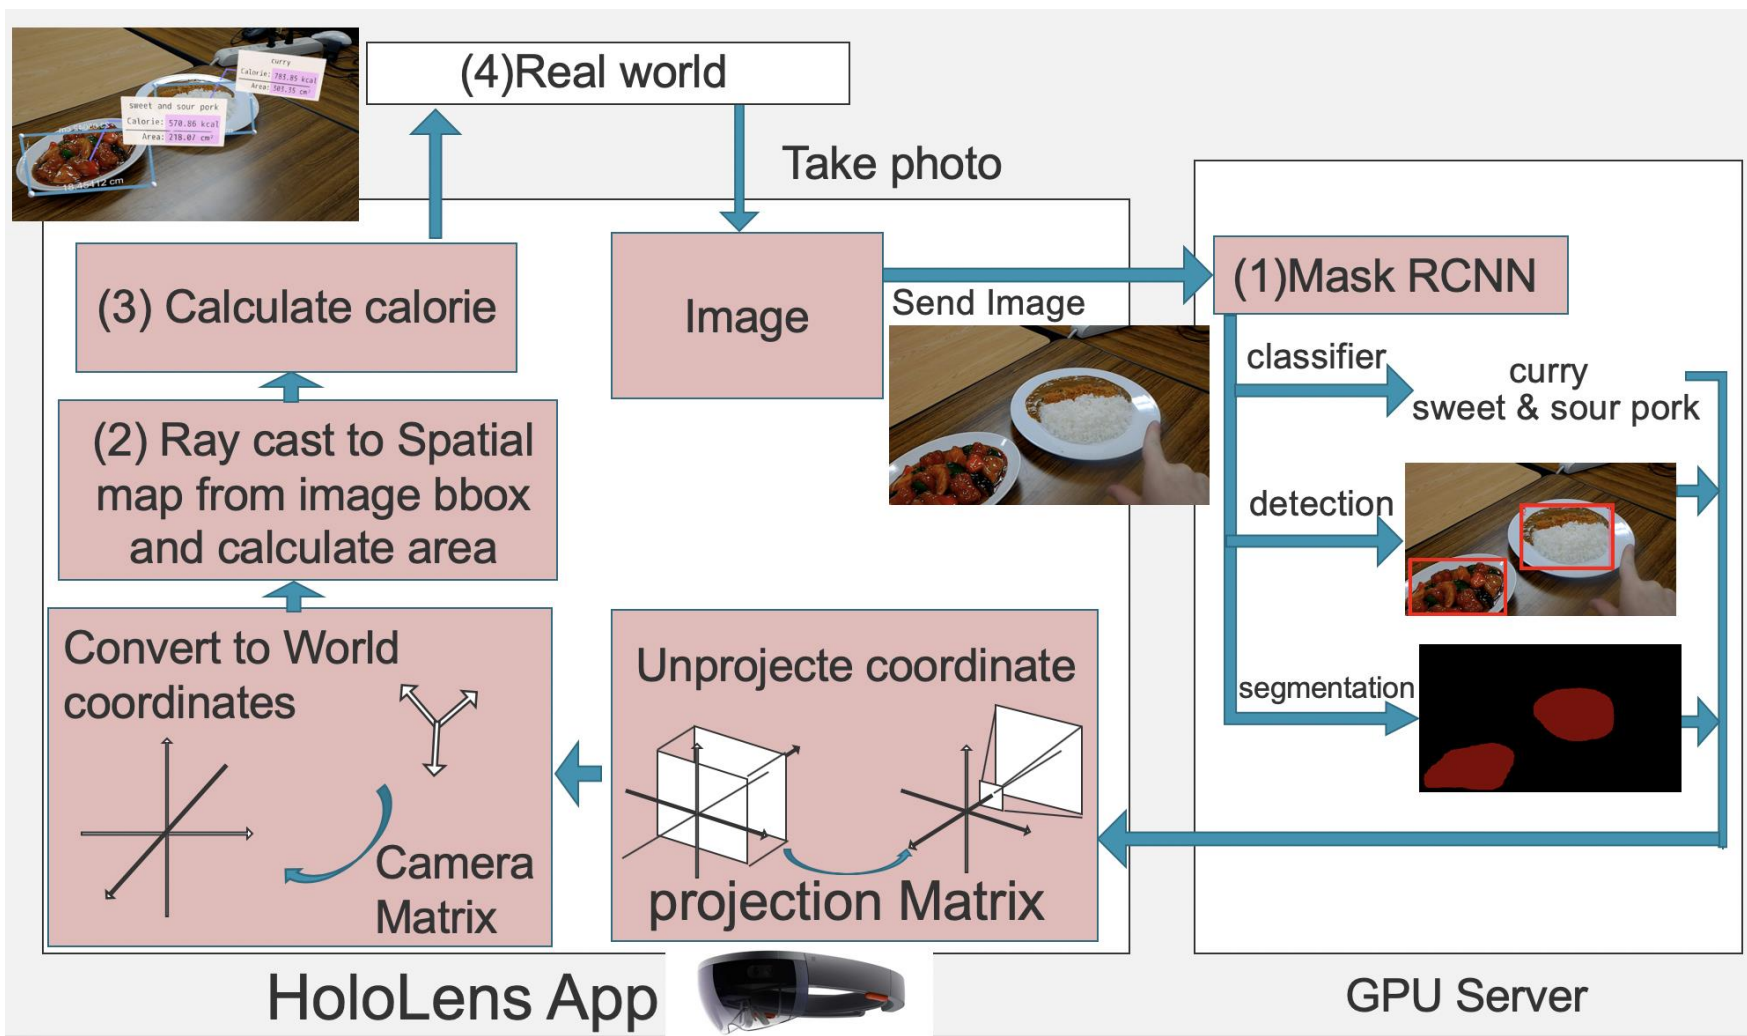

## Proposed System

- **Without manual operation**, estimate calorie based on real area for each meals at once.
- **No restrictions** on shooting methods.
- Supports **48 categories**.
- Implemented on HoloLens.

## System configuration

- This system consist mainly 4 parts.

- ① Image Recognition
- ② Actual size estimation
- ③ Calorie estimation
- ④ Showing meal information

## Image Recognition

- Using **Mask R-CNN[1]** to detect, classify and segment foods from image.
- For training, we use UEC-FoodPix[2] dataset

	AP50
Detection	42.8
Segmentation	39.1

## Actual size estimation

- Using the **camera projection matrix** to map the 2D images coordinates to 3D camera coordinates.
- Correspondence with the **environment map**, calculates where a point on an image is on the 3D world coordinates.

## Calorie estimation

- Created a **regression equation** from a dataset with known meal area and calories.
- Since the real area and meal categories are estimated, we estimate the amount of calories from them and the regression equation.

## Showing meal information

- Food category, area, and calorie information display above the meals in the MR space.
